STATE FEEDBACK CONTROL FOR STOCHASTIC NONLINEAR SYSTEMS WITH HIGH-ORDER TERMS AND TIME-VARYING DELAY

JING Qing-cui, WANG Tian-cheng

(School of Mathematics and Statistics Science, Ludong University, Yantai 264025, China)

Abstract: In this paper, we study the state feedback control problem for a class of high-order stochastic nonlinear systems with time-varying delay. Using the Lyapunov method, a suitable Lyapunov functional is constructed and combined with the stability theory of stochastic systems, we obtain a state feedback controller which can make the global asymptotical stability (GAS) in probability of the closed-loop system. System in this paper has more general high-order terms, which generalizes the previous result of global asymptotic stability in probability of a single high-order term system. The efficiency of the state-feedback controller is demonstrated by a simulation example.

Keywords: high-order terms; time-varying delay; state feedback; Lyapunov-Krasovskii theory; stochastic nonlinear.

2010 MR Subject Classification: 34D20; 35G50

1 Introduction

As we all know, the stochastic systems received more and more attention in physical applications and science. Ever since the stochastic stability theory was established and improved by Kushner, Mao, Deng and Has’minskii [1–4], the design and analysis of a backstepping controller for nonlinear stochastic systems achieved remarkable development in recent years [5–10]. The delay was also widely existed in practical system. The presence of time delay greatly complicates the stochastic control designs and makes them more difficult [11–12]. Therefore, the control design of stochastic nonlinear time-delay systems was received much attention in recent years [13–16].

In this paper, we consider the following stochastic nonlinear system with high-order terms and time-varying delay in the form

\[
\begin{align*}
\dot{x}_i &= \sum_{j=1}^{n} h_{ij}(t)x_{i+1}(t)dt + f_i(t, \bar{x}_i(t), \bar{x}_i(t-d(t)))dt + g_i^T(t, \bar{x}_i(t), \bar{x}_i(t-d(t)))d\omega, \\
\dot{x}_n &= h_n(t)u(t)dt + f_n(t, \bar{x}_n(t), \bar{x}_n(t-d(t)))dt + g_n^T(t, \bar{x}_n(t), \bar{x}_n(t-d(t)))d\omega, \\
\end{align*}
\]

Biography: Jing Qingcui (1994–), female, born at Heze, Shandong, master, major in stochastic control. E-mail:1273585330@qq.com.
where \( i = 1, 2, \ldots, n - 1 \), \( x = (x_1, x_2, \ldots, x_n)^T \in \mathbb{R}^n \) and \( u \in \mathbb{R} \) are the system state and input, respectively. \( \bar{x}_i = (x_1, x_2, \ldots, x_i)^T \), \( \bar{x}_n(t) = x(t) \), \( \bar{x}_i(t - d(t)) = (x_1(t - d(t)), x_2(t - d(t)), \ldots, x_i(t - d(t)))^T \), \( \bar{x}_n(t - d(t)) = x(t - d(t)) \); \( h_{ij}(t) : R_+ \rightarrow R_+, i = 1, 2, \ldots, n - 1; j = 1, 2, \ldots, s \), are continuous functions; \( p_j \in \mathbb{R}^{m \times d}_{\text{odd}} = \{ q \in \mathbb{R} : q \geq 1 \text{ and } q \text{ is a ratio of odd integers} \} \) is said to be the high-order of the system and \( h_{ij} x_{i+1}^{p_j} \) is high-order term of the system. \( d(t) : R_+ \rightarrow [0, d] \) is time-varying delay which satisfies \( 0 \leq d(t) \leq h < 1 \); \( \omega \) is an \( m \)-dimensional standard Wiener process defined on a probability space \((\Omega, \mathcal{F}, P)\) with \( \Omega \) being a sample space, \( \mathcal{F} \) being a filtration, and \( P \) being a probability measure; the drift terms \( f_i : R_+ \times \mathbb{R}^n \times \mathbb{R}^r \rightarrow \mathbb{R} \) and the diffusion terms \( g_i : R_+ \times \mathbb{R}^r \times \mathbb{R}^i \rightarrow \mathbb{R}^m, i = 1, 2, \ldots, n \), are assumed to be locally Lipschitz in \((\bar{x}_i(t), \bar{x}_i(t - d(t)))\) and piecewise continuous in \( t \) with \( f_i(t, 0, 0) = 0 \) and \( g_i(t, 0, 0) = 0 \).

When \( s = 1 \) (i.e., single high-order term), for this kind of stochastic nonlinear time-varying delay system (1.1), by using backstepping methods, the design of global stabilization controller achieved remarkable development [17–20]. When \( s > 1 \), system (1.1) has more general terms \( \sum_{j=1}^{s} h_{ij}(t) x_{i+1}^{p_j} \), it is more interesting since it includes the single high-order term case as a special case. When the diffusion term is zero in the stochastic nonlinear system (1.1), Wang and Zheng [21] studied the stability of this type of system for the first time and gave the state feedback controller. To the best of our knowledge, there are not any results on GAS in probability for system (1.1) at present, this paper is a promotion of previous literature.

In this paper, under the appropriate conditions on nonlinearities in drift and diffusion vector fields, the method of backstepping design and the method of power integration are combined to solve the state feedback stabilization problem for stochastic nonlinear system (1.1) with high-order terms and time-varying delay.

2 Preliminary Results

The following notations are used throughout the paper. \( R_+ \) denotes the set of all nonnegative real numbers, and \( R^n \) denotes the real \( n \)-dimensional space. For a given vector or matrix \( X, X^T \) denotes its transpose, \( \text{Tr}\{X\} \) denotes its trace when \( X \) is square, and \( |X| \) is the Euclidean norm of a vector \( X \). \( C^b_{F_0}([-d, 0]; \mathbb{R}^n) \) denotes the family of all \( F_0 \)-measurable bounded \( C([-d, 0]; \mathbb{R}^n) \)-valued random variables \( \xi = \{ \xi(\theta) : -d \leq \theta \leq 0 \} \). \( C^i \) denotes the set of all functions with continuous \( i \)th partial derivatives. \( C^{2, 1}(R^n \times [-d, \infty); R_+) \) denotes the family of all nonnegative functions \( V(x, t) \) on \( R^n \times [-d, \infty) \) which are \( C^2 \) in \( x \) and \( C^1 \) in \( t \). \( \mathcal{K} \) denotes the set of all functions: \( R_+ \rightarrow R_+ \), which are continuous, strictly increasing and vanishing at zero; \( \mathcal{K}_{\infty} \) denotes the set of all functions which are of class \( \mathcal{K} \) and unbounded.

The following definitions and lemmas are used throughout the paper.

**Definition 2.1** (see [22]) The equilibrium \( x(t) = 0 \) of the stochastic system (1.1) is said to be

(i) globally stable in probability if for any \( \varepsilon > 0 \), there exists a function \( \gamma(\cdot) \in \mathcal{K} \) such
that
\[ P\{|x(t, \phi)| < \gamma (\sup_{-d \leq s \leq 0} |\phi|) \geq 1 - \varepsilon, \forall t \geq 0, \phi \in \mathcal{C}^b_{\mathcal{F}_0}([-d, 0]; R^n)\} \{0\}; \]

(ii) globally asymptotically stable (GAS) in probability, one has
\[ P\{|x(t, \phi)| = 0\} = 1, \forall t \geq 0, \phi \in \mathcal{C}^b_{\mathcal{F}_0}([-d, 0]; R^n)\} \{0\}.

**Definition 2.2** For any given \( V(x(t), t) \in \mathcal{C}^{2,1} \) associated with stochastic system (1.1), the differential operator \( \mathcal{L} \) is defined as
\[ \mathcal{L}V = \frac{\partial V}{\partial t} + \frac{\partial V}{\partial x} f + \frac{1}{2} \text{Tr}\{g \frac{\partial^2 V}{\partial x^2} g^T\}, \]
where \( \frac{1}{2} \text{Tr}\{g \frac{\partial^2 V}{\partial x^2} g^T\} \) is called as the Hessian term of \( \mathcal{L} \).

**Lemma 2.3** (see [22]) For stochastic system (1.1), if there exist a function \( V(x(t), t) \in \mathcal{C}^{2,1}(R^n \times [-d, \infty); R_+) \), two class-\( \mathcal{K} \) functions \( \alpha_1, \alpha_2 \), and a class-\( \mathcal{K} \) function \( \alpha_3 \) such that
\[ \alpha_1(|x(t)|) \leq V(x(t), t) \leq \alpha_2(\sup_{-d \leq s \leq 0} |x(t + s)|), \]
\[ \mathcal{L}V(x(t), t) \leq -\alpha_3(|x(t)|), \]
then there exists a unique solution on \([-d, \infty)\) for (1.1), and the equilibrium \( x(t) = 0 \) is GAS in probability.

**Lemma 2.4** (see [23]) Let \( r \in R^{\geq 1}_{\text{odd}} \), and \( x, y \) be real-valued functions. One has
\[ |x^r - y^r| \leq r|x - y|(x^{r-1} + y^{r-1}) \leq c|x - y|(x^{r-1} + y^{r-1}), \]
where, if \( 1 < r < 2 \), then \( c = r \); if \( r > 2 \), then \( c = r2^{r-1} \).

**Lemma 2.5** (see [24]) For any \( x, y \in R \) and a constant \( p \geq 1 \), then
\[ |x + y|^p \leq 2^{p-1}|x^p + y^p|, \quad (|x| + |y|)^{\frac{1}{p}} \leq |x|^{\frac{1}{p}} + |y|^{\frac{1}{p}}. \]
Moreover, if \( p \) is an odd integer, then
\[ |x - y|^p \leq 2^{p-1}|x^p - y^p|, \quad |x^{\frac{1}{p}} - y^{\frac{1}{p}}| \leq 2^{1-\frac{1}{p}}|x - y|^{\frac{1}{p}}. \]

**Lemma 2.6** (see [25]) For \( x_1, \cdots, x_n \) being real variables and \( p > 0 \) being a constant, then
\[ (x_1 + \cdots + x_n)^p \leq \max\{n^{p-1}, 1\}(x_1^p + \cdots + x_n^p). \]

**Lemma 2.7** (see [23]) Let \( x, y \) be real variables, for any positive real numbers \( a, b, m \) and \( n \), the following inequality holds
\[ ax^m y^n \leq b|x|^{m+n} + \frac{n}{m+n} \left( \frac{m+n}{m} \right)^{-\frac{m}{n}} a^{\frac{m+n}{n}} b^{-\frac{m}{n}} |y|^{m+n}. \]

3 Control Design and Stability Analysis
In this technical note, we need the following assumptions

**Assumptions 1** There are positive constants \( h \) and \( \bar{h} \), such that
\[
0 < h \leq h_{ij}(t) \leq \bar{h}, 0 < \bar{h} \leq h_n(t) \leq \bar{h}.
\]

**Assumptions 2** There exist positive constants \( a_{i,m}, \tilde{a}_{i,m}, b_{i,m}, \tilde{b}_{i,m} \) \((i = 1, 2, \cdots, n; m = 1, 2, \cdots, i)\), such that
\[
|f_i(\cdot)| \leq \sum_{m=1}^{i} \sum_{j=1}^{s} a_{i,m} |x_m|^{p_j} + \sum_{m=1}^{i} \sum_{j=1}^{s} \tilde{a}_{i,m} |x_m(t-d(t))|^{p_j},
\]
\[
|g_i(\cdot)| \leq \sum_{m=1}^{i} \sum_{j=1}^{s} b_{i,m} |x_m|^{\frac{1+p_j}{2}} + \sum_{m=1}^{i} \sum_{j=1}^{s} \tilde{b}_{i,m} |x_m(t-d(t))|^{\frac{1+p_j}{2}}.
\]

**Remark 3.1** This paper considers the state-feedback control of system (1.1) with more general high-order terms \( \sum_{j=1}^{s} h_{ij}(t)x_{i+1}^{p_j} \), which is more general than the single high-order term case (see [22, 26–27]). Therefore, this paper contains more general results to some extent.

On this basis, we designed a state feedback controller of globally asymptotically stable in probability for system (1.1). At the first, we assume a set of virtual controllers \( x_1^*, x_2^*, \cdots, x_k^* \) \((1 \leq k \leq n)\) are defined by
\[
x_1^* = 0, \quad \xi_1 = x_1 - x_1^* = x_1,
\]
\[
x_2^* = -\alpha_1 \xi_1, \quad \xi_2 = x_2 - x_2^* = x_2 + \alpha_1 \xi_1,
\]
\[\vdots\]
\[
x_k^* = -\alpha_{k-1} \xi_{k-1}, \quad \xi_k = x_k - x_k^* = x_k + \alpha_{k-1} \xi_{k-1},
\]
where \( \alpha_i > 0 \) \((1 \leq i \leq k-1)\) are design parameters to be chosen later. From (1.1) and (3.3), it follows that
\[
d \xi_1 = \sum_{j=1}^{s} h_{ij}(t)x_{i+1}^{p_j} + c_{0,1} f_1(t, \bar{x}_1, \bar{x}_1(t-d(t)))dt + c_{0,1} g_1^T(t, \bar{x}_1, \bar{x}_1(t-d(t)))d\omega,
\]
\[
d \xi_i = \sum_{j=1}^{s} h_{ij}(t)x_{i+1}^{p_j} + \sum_{k=1}^{i-1} c_{i-1,k} \sum_{j=1}^{s} h_{kj} x_{k+1}^{p_j} + \sum_{k=1}^{i} c_{i-1,k} f_k(t, \bar{x}_k, \bar{x}_k(t-d(t)))dt
\]
\[+ \sum_{k=1}^{i} c_{i-1,k} g_k^T(t, \bar{x}_k, \bar{x}_k(t-d(t)))d\omega, \quad i = 2, 3, \cdots, n-1,
\]
\[
d \xi_n = (h_n(t))u + \sum_{k=1}^{n-1} c_{n-1,k} \sum_{j=1}^{s} h_{kj} x_{k+1}^{p_j} + \sum_{k=1}^{n} c_{n-1,k} f_k(t, \bar{x}_k, \bar{x}_k(t-d(t)))dt
\]
\[+ \sum_{k=1}^{n} c_{n-1,k} g_k^T(t, \bar{x}_k, \bar{x}_k(t-d(t)))d\omega,
\]
where

\[ c_{i-1,k} = \begin{cases} 
\alpha_{i-1} \cdots \alpha_k, & k = 1, 2, \ldots, i - 1, \\
1, & k = i.
\end{cases} \]

Consider the following Lyapunov-Krasovskii functional

\[ V = \frac{1}{4} \sum_{i=1}^{n} \xi_i^4 + \int_{t-d(t)}^{t} W(\xi(\sigma))d\sigma, \quad (3.5) \]

where \( W(\xi) = \sum_{i=1}^{n} \sum_{j=1}^{s} \frac{n-i+1}{2(1-h)} \xi_{i,j}^{3+p_j}. \) By (3.4), one gets

\[
\mathcal{L}V \leq \xi_3^3 h_n(t)u + \sum_{i=1}^{n} \sum_{j=1}^{s} \xi_3^3 h_{ij}(t)x_{i+1}^{p_j} + \sum_{i=2}^{n} \sum_{k=1}^{i-1} \sum_{j=1}^{s} h_{kj}x_{k+1}^{p_j} + \sum_{i=1}^{n} \xi_3^3 c_{i-1,k} h_{ij}(t)x_{i+1}^{p_j} + \frac{3}{2} \sum_{i=1}^{n} \xi_i^2 \left( \sum_{k=1}^{i} c_{i-1,k} g_k(t, \bar{x}_k, \bar{x}_k(t-d(t))) \right)^2 + W(\xi) - (1-h)W(\xi(t-d(t))) = \xi_3^3 h_n(t)u + \sum_{i=1}^{n} \sum_{j=1}^{s} \xi_3^3 h_{ij}(t)x_{i+1}^{p_j} + \sum_{i=1}^{n} \sum_{j=1}^{s} \xi_3^3 \left( h_{ij}(t)x_{i+1}^{p_j} - h_{ij}^{(p_j)}x_{i+1} \right) + \frac{3}{2} \sum_{i=1}^{n} \xi_i^2 \left( \sum_{k=1}^{i} c_{i-1,k} g_k(t, \bar{x}_k, \bar{x}_k(t-d(t))) \right)^2 + W(\xi) - (1-h)W(\xi(t-d(t))). \quad (3.6)
\]

Next, we estimate the right side of (3.6). The following propositions supply these estimates, with their respective proofs located in Appendix.

**Proposition 1** There exists a positive constant \( \beta_i \) such that

\[
\sum_{j=1}^{s} \xi_3^3 \left( h_{ij}(t)x_{i+1}^{p_j} - h_{ij}^{(p_j)}x_{i+1} \right) \leq \frac{1}{4(1-h)} \sum_{j=1}^{s} \xi_i^{3+p_j} + \beta_{i+1} \sum_{j=1}^{s} \xi_i^{3+p_j}, i = 1, 2, \ldots, n - 1. \quad (3.7)
\]

**Proposition 2** There exists a positive constant \( \eta_i \) such that

\[
\sum_{k=1}^{i-1} \sum_{j=1}^{s} \xi_3^3 h_{kj}x_{k+1}^{p_j} \leq \frac{1}{4(1-h)} \sum_{k=1}^{i} \sum_{j=1}^{s} \xi_k^{3+p_j} + \eta_i \sum_{j=1}^{s} \xi_i^{3+p_j}, i = 2, 3, \ldots, n. \quad (3.8)
\]

**Proposition 3** There exists a positive constant \( \gamma_i \) such that

\[
\sum_{k=1}^{i} \sum_{j=1}^{s} c_{i-1,k} f_k(t, \bar{x}_k, \bar{x}_k(t-d(t))) \leq \frac{1}{4(1-h)} \sum_{k=1}^{i} \sum_{j=1}^{s} \xi_k^{3+p_j} + \frac{1}{4} \sum_{k=1}^{i} \sum_{j=1}^{s} \xi_k^{3+p_j}(t-d(t)) + \gamma_i \sum_{j=1}^{s} \xi_i^{3+p_j}, i = 1, 2, \ldots, n. \quad (3.9)
\]
Proposition 4 There exists a positive constant $\mu_i$ such that

$$
\frac{3}{2} \xi_i^2 \left( \sum_{k=1}^{i} c_{-1,k} g_k(t, x_k, \bar{x}_k(t - d(t))) \right)^2 \leq \frac{1}{4(1 - h)} \sum_{k=1}^{i} \sum_{j=1}^{s} \xi_k^{3+p_j} + \frac{1}{4} \sum_{k=1}^{i} \sum_{j=1}^{s} \xi_k^{3+p_j} (t - d(t)) + \mu_i \sum_{j=1}^{s} \xi_j^{3+p_j}, \ i = 1, 2, \ldots, n.
$$

(3.10)

We can obtain the following formula by combing (3.6) with (3.7)–(3.10)

$$
L V \leq \xi_n^3 h_n(t) u + \sum_{i=1}^{n-1} \sum_{j=1}^{s} \xi_i^3 h_i x_{i+1}^{p_j} + \sum_{i=1}^{n-1} \left( \frac{1}{4(1 - h)} \sum_{j=1}^{s} \xi_i^{3+p_j} + \beta_i \sum_{j=1}^{s} \xi_i^{3+p_j} \right)
$$

$$
+ \sum_{i=2}^{n} \left( \frac{1}{4(1 - h)} \sum_{j=1}^{s} \xi_i^{3+p_j} + \eta_i \sum_{j=1}^{s} \xi_i^{3+p_j} \right) + \sum_{i=1}^{n} \left( \frac{1}{2(1 - h)} \sum_{j=1}^{s} \xi_i^{3+p_j} \right)
$$

$$
+ \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{s} \xi_i^{3+p_j} (t - d(t)) + (\gamma_i + \mu_i) \sum_{j=1}^{s} \xi_i^{3+p_j} + W(\xi) - (1 - h) W(\xi(t - d(t)))
$$

$$
= \xi_n^3 h_n(t) u + \sum_{i=1}^{n-1} \sum_{j=1}^{s} \xi_i^3 h_i x_{i+1}^{p_j} + \sum_{i=1}^{n-1} \left( \frac{1}{4(1 - h)} \sum_{j=1}^{s} \xi_i^{3+p_j} \right)
$$

$$
+ \sum_{i=2}^{n} \beta_i \sum_{j=1}^{s} \xi_i^{3+p_j} + \sum_{i=1}^{n} \left( \frac{1}{4(1 - h)} \sum_{j=1}^{s} \xi_i^{3+p_j} \right) + \sum_{i=1}^{n} \eta_i \sum_{j=1}^{s} \xi_i^{3+p_j} + \sum_{i=1}^{n} \left( \frac{n - i + 1}{2(1 - h)} \sum_{j=1}^{s} \xi_i^{3+p_j} \right)
$$

$$
+ \sum_{i=1}^{n} \left( \frac{n - i + 1}{2(1 - h)} \sum_{j=1}^{s} \xi_i^{3+p_j} (t - d(t)) + \sum_{i=1}^{n} (\gamma_i + \mu_i) \sum_{j=1}^{s} \xi_i^{3+p_j} \right)
$$

$$
+ \sum_{i=1}^{n} \left( \frac{n - i + 1}{2(1 - h)} \sum_{j=1}^{s} \xi_i^{3+p_j} - (1 - h) \sum_{i=1}^{n} \sum_{j=1}^{s} \xi_i^{3+p_j} (t - d(t)) \right)
$$

$$
= [h_n(t) - \frac{1}{2} \xi_n^3 u + \xi_n^3 h u + \left( \frac{1}{1 - h} + \beta_n + \eta_n + \gamma_n + \mu_n \right) \sum_{j=1}^{s} \xi_j^{p_j}] + \xi_n^3 \sum_{j=1}^{s} \left[ h x_{i+1}^{p_j} + \left( \frac{5n}{4(1 - h)} + \gamma_i + \mu_i \right) \xi_i^{p_j} \right]
$$

$$
+ \sum_{i=2}^{n} \xi_i^3 \sum_{j=1}^{s} \left[ h x_{i+1}^{p_j} + \left( \frac{5(n - i + 1)}{4(1 - h)} + \beta_i + \eta_i + \gamma_i + \mu_i \right) \xi_i^{p_j} \right].
$$

(3.11)

According to the above inequalities, one obtains the virtual controllers

$$
x_{i}^{*} = -\left( \frac{1}{2} (\lambda_1 + \frac{5n}{4(1 - h)} + \gamma_1 + \mu_1) \right) \xi_i = -\alpha_1 \xi_i,
$$

(3.12)

where $\alpha_1 = \left( \frac{1}{2} (\lambda_1 + \frac{5n}{4(1 - h)} + \gamma_1 + \mu_1) \right)^{1/\gamma}, \ p_\gamma = \min_{1 \leq j \leq s} p_j,$

$$
x_{i+1}^{*} = -\left( \frac{1}{2} (\lambda_1 + \frac{5(n - i + 1)}{4(1 - h)} + \beta_i + \eta_i + \gamma_i + \mu_i) \right) \xi_i, \ 2 \leq i \leq n - 1.
$$

(3.13)
where \( \alpha_i = \left( \frac{1}{2} (\lambda_i + \frac{5(n-i+1)}{4(1-h)}) + \beta_i + \eta_i + \gamma_i + \mu_i) \right)^{\frac{1}{p_i}} \) \((2 \leq i \leq n-1)\), and the controller
\[
u = -\sum_{j=1}^{s} \left( \frac{1}{2} (\lambda_n + \frac{1}{1-h}) \beta_n + \eta_n + \gamma_n + \mu_n) \right)^{\frac{1}{p_j}} \xi_n P_j = -\sum_{j=1}^{s} \alpha_n P_j \xi_n P_j, \tag{3.14}\]
where \( \alpha_n = \left( \frac{1}{2} (\lambda_n + \frac{1}{1-h}) \beta_n + \eta_n + \gamma_n + \mu_n) \right)^{\frac{1}{p_j}} \lambda_i \geq h \) \((i = 1, 2, \ldots, n)\) are positive constants. According to \( h_n(t) - h \xi_n^3 \leq 0 \), we can obtain the following inequality by substituting (3.12), (3.13), (3.14) into (3.12)
\[
\mathcal{L}V \leq -\sum_{i=1}^{n} \sum_{j=1}^{s} \lambda_i \xi_i^{3+p_j}. \tag{3.15}\]

Based on (3.5) and (3.15), we state the main result in this paper.

**Theorem 3.1** Under Assumptions 1 and 2, there is a state feedback controller (3.14) such that the closed-loop stochastic system consisting of (1.1) and controller (3.14) has a global unique solution, and the equilibrium at the origin is GAS in probability.

**Proof** By \( V = \frac{1}{4} \sum_{i=1}^{n} \xi_i^4 + \int_{t-d(t)}^{t} W(\xi(\sigma))d\sigma \geq \frac{1}{4} \sum_{i=1}^{n} \xi_i^4 \) and Lemma 2.6, one has
\[
\frac{1}{4} \sum_{i=1}^{n} \xi_i^4 \geq \frac{1}{4n} \left( \sum_{i=1}^{n} \xi_i^2 \right)^{4}. \]
According to Lemma 2.3, there is a \( \mathcal{K}_\infty \) function \( \alpha_1(\xi) = \frac{1}{4n} \xi^4 \) such that \( \alpha_1(\xi) \leq V(\xi) \). Furthermore, by mean value theorem, one obtains
\[
V = \frac{1}{4} \sum_{i=1}^{n} \xi_i^4 + \int_{t-d(t)}^{t} W(\xi(\sigma))d\sigma \leq \frac{1}{4} \sum_{i=1}^{n} \sup_{-d \leq s \leq 0} \xi_i^4(t+s) + \frac{nd}{2(1-h)} \sum_{i=1}^{n} \sum_{j=1}^{s} \sup_{-d \leq s \leq 0} \xi_i^{3+p_j}(t+s) \leq \frac{1}{4} \left( \sum_{i=1}^{n} \sup_{-d \leq s \leq 0} \xi_i^2(t+s) \right)^{4} + \frac{nd}{2(1-h)} \sum_{j=1}^{s} \left( \sum_{i=1}^{n} \sup_{-d \leq s \leq 0} \xi_i^2(t+s) \right)^{3+p_j}. \]
Define another \( \mathcal{K}_\infty \) function \( \alpha_2(\xi) = \frac{1}{4} \xi^4 + \frac{nd}{2(1-h)} \sum_{j=1}^{s} \xi^{3+p_j} \), we have
\[
\alpha_2(\sup_{-d \leq s \leq 0} \xi(t+s)) = \frac{1}{4} \left( \sup_{-d \leq s \leq 0} |\xi(t+s)| \right)^{4} + \frac{nd}{2(1-h)} \sum_{j=1}^{s} \left( \sup_{-d \leq s \leq 0} |\xi(t+s)| \right)^{3+p_j}, \]
then \( V(\xi, t) \leq \alpha_2(\sup_{-d \leq s \leq 0} |\xi(t+s)|) \). By \( \alpha_1(\xi) \leq V(\xi) \leq \alpha_2(\sup_{-d \leq s \leq 0} |\xi(t+s)|) \) and (3.15), we can know that the conditions of Lemma 2.3 are founded, so there is a global unique solution for the closed-loop system consisting of (1.1) and (3.14), meanwhile, the equilibrium \( \xi = 0 \) is GAS in probability.
Remark 3.2 In the procedure of design and analysis of controller, the main obstacles are the appearance of high-order terms, time-varying delay, nonlinear assumptions and Hessian terms, which will unavoidably produce many more nonlinear terms and inequalities, and how to deal with them is not an easy work.

4 A Simulation Example

In this section, a example is given to illustrate the effectiveness of the proposed design approach.

Consider the following stochastic nonlinear system

\[ dx_1 = \left( (1.1 + 0.1 \sin(t))x_2 + (1.05 + \frac{1}{20}\sin(t))x_2^2 + \frac{1}{4}x_1 \sin x_1 + \frac{1}{4}x_1^2(t - d(t)) \right) dt + \frac{1}{6}x_1^2(t - d(t)) d\omega, \]

\[ dx_2 = \left( (1.2 + 0.2 \cos(t))u + \frac{1}{6}(x_1^2 + x_2^2) + \frac{1}{3}x_2^2(t - d(t)) \right) dt + \frac{1}{7}x_2^2(t - d(t)) d\omega, \quad (4.1) \]

where \( p_1 = 1, p_2 = \frac{9}{7}, d(t) = \frac{1 + \sin(t)}{10}, f_1(t, x_1, x_1(t - d(t))) = \frac{1}{4}x_1 \sin x_1 + \frac{1}{4}x_1^2(t - d(t)), \)

\( f_2(t, \bar{x}_2, \bar{x}_2(t - d(t))) = \frac{1}{6}(x_1^2 + x_2^2) + \frac{1}{3}x_2^2(t - d(t)) \) and \( g_1(t, x_1, x_1(t - d(t))) = \frac{1}{4}x_1^2(t - d(t)), \)

\( g_2(t, \bar{x}_2, \bar{x}_2(t - d(t))) = \frac{1}{7}x_2^2(t - d(t)) \). Since \( s = 2 \) in (4.1), obviously, the previous methods are not applicable to system (4.1). It is easy to verify that Assumptions 1 and 2 are satisfied. That is,

\[ |f_1(t, x_1, x_1(t - d(t)))| \leq \frac{1}{4}|x_1|^2 + \frac{1}{4}|x_1(t - d(t))|^2, \]

\[ |f_2(t, \bar{x}_2, \bar{x}_2(t - d(t)))| \leq \frac{1}{6}(|x_1|^2 + |x_2|^2) + \frac{1}{3}|x_2(t - d(t))|^2, \]

\[ |g_1(t, x_1, x_1(t - d(t)))| = \frac{1}{6}|x_1(t - d(t))|^2, \]

\[ |g_2(t, \bar{x}_2, \bar{x}_2(t - d(t)))| = \frac{1}{7}|x_2(t - d(t))|^2. \]

Choosing \( h = 0.1 \), by following the design procedure in ‘Control design and stability analysis’, we obtain the controller

\[ u = -8.54(x_2 + 3.95x_1) - 48.27(x_2 + 3.95x_1)^2. \quad (4.2) \]

In the simulation, we choose \( \lambda_1 = \lambda_2 = 1 \) and the initial values \( x_1(0) = -1, x_2(0) = -1 \). Figure 1 and figure 2 give the system response of the closed-loop system consisting of (4.1) and (4.2), from which, the efficiency of the controller is demonstrated.

5 Conclusion

The main work of this paper is to give the state-feedback controller for the stochastic nonlinear systems with high-order terms and time-varying delay. This controller ensures that the equilibrium point of the whole system is globally asymptotically stable in probability. In the future work, there are still a lot of problems to be solved. One is to consider more...
general systems with weaker assumptions. Another is to design an output feedback controller for system (1.1). The third is to deal with the stability of such a type of upper triangular system. These will be the focus of the next work.

一类高阶随机非线性时变时滞系统状态反馈控制

井青翠, 王天成

(鲁东大学数学与统计科学学院, 山东 烟台 264025)

摘要: 本文研究了一类高阶随机非线性时变时滞系统的状态反馈控制问题。通过构造恰当的李雅普诺夫泛函，并结合随机系统的稳定性理论，获得了一个能使得整个闭环系统为概率全局渐近稳定的反馈控制器。本文系统具有更一般的高阶项，推广了以往单一高阶项系统概率全局渐近稳定的结果。数值仿真验证了所提状态反馈控制器方案的有效性。

Appendix

In Appendix, we give the proofs of Propositions 1–4.

Proof of Proposition 1  With the help of (3.3), we can know that $-\sum_{j=1}^{s} \xi_{i}^{3} x_{i+1}^{p_{j}} \geq 0$.

It follows that

$$\sum_{j=1}^{s} \xi_{i}^{3} (h_{ij} x_{i+1}^{p_{j}} - x_{i+1}^{p_{j}}) \leq \sum_{j=1}^{s} |\xi_{i}^{3} h_{ij} x_{i+1}^{p_{j}} - \xi_{i}^{3} x_{i+1}^{p_{j}}| \leq \sum_{j=1}^{s} |\xi_{i}^{3} h_{ij} x_{i+1}^{p_{j}}|$$

$$\leq \bar{h} \sum_{j=1}^{s} |\xi_{i}^{3} (x_{i+1}^{p_{j}} - x_{i+1}^{p_{j}})| = \bar{h} \sum_{j=1}^{s} |\xi_{i}^{3} x_{i+1}^{p_{j}} - x_{i+1}^{p_{j}}|.$$

By $p_{j} \geq 1$, Lemmas 2.4, 2.7 and (3.3), one has

$$\bar{h} \sum_{j=1}^{s} |\xi_{i}^{3} (|x_{i+1}^{p_{j}}| - |x_{i+1}^{p_{j}}|)| \leq \bar{h} c |\xi_{i}|^{3} |x_{i+1}^{p_{j}}| \sum_{j=1}^{s} |\xi_{i}^{p_{j}-1} + x_{i+1}^{p_{j}-1}|$$

$$\leq \bar{h} c \sum_{j=1}^{s} |\xi_{i}|^{3} |x_{i+1}^{p_{j}}| |\xi_{i+1}^{p_{j}-1}| + \alpha_{i}^{p_{j}-1} |\xi_{i}^{p_{j}-1}| = \sum_{j=1}^{s} \bar{h} c |\xi_{i}|^{3} |\xi_{i+1}^{p_{j}}| + \sum_{j=1}^{s} \bar{h} c \alpha_{i}^{p_{j}-1} |\xi_{i}^{2+p_{j}}| |\xi_{i+1}^{p_{j}}|$$

$$\leq \frac{1}{8(1-h)} \sum_{j=1}^{s} \xi_{i}^{3+p_{j}} + \beta_{i+1,1} \sum_{j=1}^{s} \xi_{i}^{3+p_{j}} + \frac{1}{8(1-h)} \sum_{j=1}^{s} \xi_{i}^{3+p_{j}} + \beta_{i+1,2} \sum_{j=1}^{s} \xi_{i}^{3+p_{j}}$$

$$= \frac{1}{4(1-h)} \sum_{j=1}^{s} \xi_{i}^{3+p_{j}} + \beta_{i+1} \sum_{j=1}^{s} \xi_{i}^{3+p_{j}} \quad (\beta_{i+1} = \beta_{i+1,1} + \beta_{i+1,2}),$$

where $\beta_{i+1,1}, \beta_{i+1,2}$ are positive constants.

Proof of Proposition 2  By Lemma 2.5 and (3.3), one has

$$\sum_{j=1}^{s} |x_{i+1}^{p_{j}}| = \sum_{j=1}^{s} |\xi_{i+1}^{p_{j}} - \alpha_{i}^{p_{j}}| \leq \sum_{j=1}^{s} s_{i} (|\xi_{i}^{p_{j}}| + |\xi_{i+1}^{p_{j}}|), \quad (5.1)$$

where $s_{i} = 2^{p_{j}-1} \max\{1, |\alpha_{i}^{p_{j}}|\}$, and define $s_{0} = 1$. According to (5.1), we deduce that

$$\sum_{k=1}^{i-1} \sum_{j=1}^{s} h_{kj} x_{k+1}^{p_{j}} \leq |\xi_{i}^{3}| \sum_{k=1}^{i-1} \sum_{j=1}^{s} c_{i-1,k} h_{s_{k}} (|\xi_{k}^{p_{j}}| + |\xi_{k+1}^{p_{j}}|)$$

$$= \sum_{k=1}^{i} \sum_{j=1}^{s} |l_{i,k}| \xi_{i}^{3} |\xi_{k}^{p_{j}}|,$$

where

$$l_{i,k} = \begin{cases} c_{i-1,k} h_{s_{k}} & k = 1, \\ c_{i-1,k} h_{s_{k}} + c_{i-1,k-1} h_{s_{k-1}} & k = 2, 3, \ldots, i - 1, \\ c_{i-1,k-1} h_{s_{k-1}} & k = i. \end{cases}$$
By Lemma 2.7, one has
\[
\sum_{j=1}^{s} l_{i,k} |\xi_{i,j}|^{3} |\xi_{k,j}| \leq \frac{1}{4(1-h)} \sum_{j=1}^{s} \xi_{j}^{3+p_{j}} + \eta_{i,k} \sum_{j=1}^{s} \xi_{i,j}^{3+p_{j}}.
\]
So we have
\[
\xi_{i}^{3} \sum_{k=1}^{i-1} c_{i-1,k} \sum_{j=1}^{s} h_{k,j} x_{k,j+1} \leq \sum_{k=1}^{i-1} \sum_{j=1}^{s} \frac{1}{4(1-h)} \xi_{k,j}^{3+p_{j}} + \eta_{i,k} \sum_{j=1}^{s} \xi_{i,j}^{3+p_{j}},
\]
where \(\eta_{i} = \sum_{k=1}^{i-1} \eta_{i,k}\), and \(\eta_{i,k}\) is associated with \(l_{i,k}\).

**Proof of Proposition 3** We prove (3.9). By (3.2) and (5.1), one can obtain
\[
\xi_{i}^{3} \sum_{k=1}^{i} c_{i-1,k} f_{k}(t, \bar{x}_{k}, \bar{x}_{k}(t-d(t)))
\]
\[
\leq |\xi_{i}|^{3} \sum_{k=1}^{i} c_{i-1,k} \sum_{j=1}^{s} \sum_{m=1}^{s} (a_{k,j} |x_{j,p_{m}} + \tilde{a}_{k,j}|x_{j}(t-d(t))|^{p_{m}})
\]
\[
= \sum_{j=1}^{i} \sum_{k=j}^{i} a_{k,j} c_{i-1,k} \sum_{m=1}^{s} |\xi_{i,j}|^{3} |x_{j,p_{m}} + \sum_{j=1}^{i} \sum_{k=j}^{i} \tilde{a}_{k,j} c_{i-1,k} \sum_{m=1}^{s} |\xi_{i,j}|^{3} |x_{j}(t-d(t))|^{p_{m}}
\]
\[
\leq \sum_{k=1}^{i} p_{i,k} \sum_{m=1}^{s} |\xi_{i,j}|^{3} |x_{j}|^{p_{m}} + \sum_{k=1}^{i} q_{i,k} \sum_{m=1}^{s} |\xi_{i,j}|^{3} |x_{k}(t-d(t))|^{p_{m}},
\]
where
\[
p_{i,k} = \begin{cases} 
  s_{k-1} \sum_{j=k}^{s} a_{j,k} c_{i-1,j} + s_{k} \sum_{j=k+1}^{i} a_{j,k+1} c_{i-1,j}, & k = 1, 2, \cdots, i - 1, \\
  s_{k-1} \sum_{j=k}^{i} a_{j,k} c_{i-1,j}, & k = i;
\end{cases}
\]
\[
q_{i,k} = \begin{cases} 
  s_{k-1} \sum_{j=k}^{s} \tilde{a}_{j,k} c_{i-1,j} + s_{k} \sum_{j=k+1}^{i} \tilde{a}_{j,k+1} c_{i-1,j}, & k = 1, 2, \cdots, i - 1, \\
  s_{k-1} \sum_{j=k}^{i} \tilde{a}_{j,k} c_{i-1,j}, & k = i.
\end{cases}
\]
From Lemma 2.7, such that
\[
p_{i,k} \sum_{m=1}^{s} |\xi_{i,j}|^{3} |x_{j}|^{p_{m}} \leq \frac{1}{4(1-h)} \sum_{m=1}^{s} \xi_{k}^{3+p_{m}} + \tilde{p}_{i,k} \sum_{m=1}^{s} \xi_{i,j}^{3+p_{m}},
\]
\[
q_{i,k} \sum_{m=1}^{s} |\xi_{i,j}|^{3} |x_{k}(t-d(t))|^{p_{m}} \leq \frac{1}{4} \sum_{m=1}^{s} \xi_{k}^{3+p_{m}} (t-d(t)) + \tilde{q}_{i,k} \sum_{m=1}^{s} \xi_{i,j}^{3+p_{m}}.
\]
So we have
\[
\xi_{i}^{3} \sum_{k=1}^{i} c_{i-1,k} f_{k}(t, \bar{x}_{k}, \bar{x}_{k}(t-d(t)))
\]
\[
\leq \sum_{k=1}^{i} \sum_{m=1}^{s} \frac{1}{4(1-h)} \xi_{k}^{3+p_{m}} + \sum_{k=1}^{i} \sum_{m=1}^{s} \frac{1}{4} \xi_{k}^{3+p_{m}} (t-d(t)) + \gamma_{i} \sum_{m=1}^{s} \xi_{i,j}^{3+p_{m}},
\]
where \(\gamma_i = \sum_{k=1}^{i} (\tilde{p}_{i,k} + \tilde{q}_{i,k})\), \(\tilde{p}_{i,k}\) is associated with \(p_{i,k}\) and \(\tilde{q}_{i,k}\) is associated with \(q_{i,k}\).

**Proof of Proposition 4** We prove (3.10). Similar to Proposition 3. According to (3.2), Lemmas 2.5, 2.6 and 2.7, we deduce that

\[
\frac{3}{2} \xi_i^2 \left( \sum_{k=1}^{i} c_{i-1,k} g_k(t, \tilde{x}_k, \tilde{x}_k(t - d(t))) \right)^2 \\
\leq \sum_{k=1}^{i} \sum_{m=1}^{s} \frac{1}{4(1-h)} \xi_k^{3+p_m} + \sum_{k=1}^{i} \sum_{m=1}^{s} \frac{1}{4} \xi_k^{3+p_m} (t - d(t)) + \mu_i \sum_{m=1}^{s} \xi_i^{3+p_m},
\]

where \(\mu_i\) is a positive constant.
